Project's Final Report

FlirtNet: We Meet. We Flirt. We Love.

Date: December 29, 2025

Group Members:

1. **Jiachen Pan** (20233802046) - Backend & Frontend Engineer, Product Manager, UI Design
2. **Junrui Liang** (20233802068) - Backend Engineer, UI Design
3. **Hongjia Huang** (20223802016) - Database Design
4. **Junlin Li** (20233802058) - Product Manager, Frontend Engineer
5. **Yueshen Wang** (20233802018) - Backend Engineer

Acknowledgments

We would like to express our deepest gratitude to our professor for the invaluable guidance and feedback throughout the duration of this Software Design course. The insights into architectural patterns and design methodologies were instrumental in shaping FlirtNet.

We also thank the open-source community, particularly the developers of React, FastAPI, and Socket.IO, whose robust tools made this rapid development possible. Finally, a special thanks to the "DeepSeek" team for providing the powerful LLM API that serves as the brain behind our Humanity Caring features.

Abstract

FlirtNet is a next-generation dating discovery platform designed to address the emotional disconnection prevalent in modern dating applications. While traditional platforms like Tinder and Bumble focus on superficial matching mechanisms ("swiping"), they often fail to support users through the subsequent stages of relationship building—conversation, connection, and even closure. FlirtNet fills this gap by introducing a "Humanity Caring" philosophy, guiding users through a complete lifecycle: **Meet, Flirt, Love, and Heal**.

The system is built as a responsive web application using a modern technology stack: **React** for the frontend, **FastAPI** for the backend, and **Socket.IO** for real-time communication. Key innovations include:

1. **Wingman**: A real-time conversation coach that helps shy users flirt with confidence.
2. **Miss Ex**: A "closure simulator" that helps users process breakups by simulating conversations with a past partner using style-transfer AI.
3. **Datemate System**: A transition mechanism to turn random encounters into permanent connections.
4. **Safety Monitor**: A proactive protection system that detects and blocks harassment in real-time.

This report details the complete software development lifecycle of FlirtNet, from problem identification and requirements specification to system architecture, database design, implementation of complex algorithms, and

final testing. The result is a robust, scalable, and emotionally intelligent platform that redefines how technology can support human connection.

Chapter 1: Introduction

Chapter 1: Introduction

1.1 Project Overview

FlirtNet is a revolutionary social discovery platform that departs from the transactional nature of modern dating applications to embrace a philosophy of "Humanity Caring." In an era where human connection is often reduced to a binary choice on a screen, FlirtNet aims to restore the emotional depth and procedural support necessary for healthy relationship development. The platform is structured around the four critical stages of a romantic journey: **Meet, Flirt, Love, and Heal**.

Unlike traditional "swipe-and-ghost" platforms, FlirtNet acts as a digital companion. It recognizes that meeting someone is only the first hurdle; the subsequent stages of communication, commitment, and even the processing of loss require guidance and care. By leveraging Artificial Intelligence not as a replace of human emotion, but as a scaffold for it, FlirtNet provides users with the tools they need to navigate the complexities of modern romance with confidence and safety.

1.2 System Purpose

The primary purpose of FlirtNet is to lower the emotional and social barriers to entry for meaningful interaction. Our research indicates that a significant portion of the "Gen Z" and "Alpha" demographics suffer from heightened social anxiety, often exacerbated by the high-pressure environment of competitive dating apps. FlirtNet serves as:

- **A Practice Ground**: Allowing users to build social skills in a low-stakes "Practice Mode."
- **A Supportive Coach**: Providing real-time conversational assistance via the AI Wingman.
- **A Safe Haven**: Utilizing proactive safety monitoring to filter out toxic behavior before it reaches the victim.
- **An Emotional Mirror**: Offering tools like "Miss Ex" to help users reflect and find closure after breakups, preventing the cycle of "rebound" relationships driven by unresolved grief.

1.3 Problem Statement

The "Dating App Crisis" is a well-documented sociological phenomenon. Despite the hundreds of millions of users on platforms like Tinder, Bumble, and Hinge, loneliness rates continue to climb. We have identified four fundamental failures in existing software design:

1. **The Cold Start Problem and Interaction Anxiety**: Most apps assume that once a match is made, the users are socially capable of sustaining a conversation. In reality, the "What do I say first?" anxiety leads to a 60% match-to-ghost conversion rate.
2. **The Commodification of Connection**: Swiping mechanisms treat humans as retail products. This leads to "Choice Overload," where users are so overwhelmed by options that they never fully invest in any single individual.
3. **The Toxicity Gap**: Traditional moderation is reactive. A user must be insulted or harassed *before* they can report the offender. In a "Humanity Caring" model, the system should prevent the initial blow.
4. **The Breakup Void**: When a relationship ends on a typical app, the user is simply "unmatched." This abrupt disconnection mirrors the traumatic experience of "ghosting" in real life, offering no psychological buffer or closure mechanism.

1.4 Objectives

To solve these problems, the FlirtNet project set out with the following technical and social objectives:

- **Integrated Life Cycle Management**: Develop a unified platform that handles the transition from random encounter to committed "Datemate" and beyond.
- **Contextual AI Intelligence**: Implement an LLM-driven "Wingman" that understands the nuance of a specific conversation rather than offering generic pick-up lines.
- **Liquid Glass UI Design**: Create a user interface that utilizes light, transparency, and soft colors to evoke a "safe space" feeling, distancing itself from the high-contrast, aggressive branding of hookup-oriented apps.
- **Proactive Safety Architecture**: Design a backend that analyzes message sentiment in real-time to protect users from verbal abuse.
- **Emotional Support Modules**: Build the "Miss Ex" simulator to provide a safe, private environment for users to process their feelings post-breakup.

1.5 Scope

The scope of this project includes the architectural design and full-stack implementation of a web-based responsive application.

- **Frontend Development**: Built using React and Vite, focusing on performance and the implementation of custom CSS Glassmorphism.
- **Backend Engineering**: A FastAPI-based asynchronous server capable of handling high-frequency Socket.IO events for real-time chat and matching.
- **AI Integration Layer**: A middleware service that interacts with the DeepSeek API, managing conversation history context and prompt optimization.
- **Database Management**: A relational SQLite schema designed for rapid prototyping, with clear migration paths to PostgreSQL for production scaling.
- **Security & Safety**: Implementation of JWT-based authentication and AI-driven content moderation.

1.6 Stakeholders

- **End Users**: Individuals seeking companionship who value emotional intelligence and safety in their digital interactions.
- **Moderators**: AI-augmented administrators who can focus on complex disputes while the system handles routine harassment detection.
- **Developers**: The engineering team tasked with balancing the high latency of LLM calls with the low latency required for real-time chat.
- **Investors/University Stakeholders**: Those interested in the commercial and social viability of a platform that prioritizes "Humanity Caring" over simple engagement metrics.

Chapter 2: Background / Literature Review

2.1 Evolution of Online Dating

The history of computer-mediated matchmaking dates back further than most realize. In the mid-1960s, projects like "Operation Match" at Harvard used punch cards and mainframe computers to pair students based on questionnaire data. This **First Wave** of online dating focused on algorithmic compatibility, the idea that a sufficiently complex set of inputs could predict romantic success. Platforms like Match.com (1995) and eHarmony (2000) perfected this model, requiring users to fill out hundreds of fields before ever seeing a potential partner.

The **Second Wave** arrival with the launch of the iPhone and the subsequent rise of Tinder (2012) changed the paradigm. Location-based services and the "swipe" interface shifted the focus from deep compatibility to immediate physical attraction and gamified engagement. While this lowered the barrier to entry, it created significant sociological side effects, including "Dating App Fatigue" and a culture of "Ghosting." Users began to report that while they were meeting more people, the quality of those interactions was significantly lower.

We are currently in the **Third Wave**: AI-assisted discovery. In this new era, the goal is not just to match users, but to support the interaction after the match occurs. Platforms are beginning to experiment with AI icebreakers and profile polishing, but few have integrated AI as a persistent "Humanity Caring" companion throughout the relationship lifecycle. FlirtNet is built to lead this third wave by addressing the interaction deficit head-on.

2.2 Sociological Context: The Paradox of Choice

Sociologist Barry Schwartz's "The Paradox of Choice" provides a critical theoretical framework for our project. In traditional dating markets, users have a limited pool of candidates. In a digital market, the pool is perceived as infinite. This infinity leads to three negative outcomes:

1. **Regret and Anticipatory Regret**: Users often feel that no matter who they talk to, there might be a "better" person just one swipe away.
2. **Opportunity Costs**: Every hour spent talking to one match is an hour not spent swiping for others.
3. **Escalation of Expectations**: Users become less tolerant of minor flaws because the market seems to provide a "perfect" person if they just keep looking.

FlirtNet mitigates these effects by introducing the **"Datemate"** status—a symbolic commitment within the app that encourages users to stop "looking" and start "building."

2.3 Existing Systems Analysis

| Feature | Tinder | Bumble | Omegle | FlirtNet |

| :--- | :--- | :--- | :--- | :--- |

| **Logic** | Visual/Swipe | Visual/Swipe | Random/Video | **Philosophy-Driven** |

| **Pace** | Rapid/Transient | Rapid/Controlled | Chaotic/Ephemeral | **Guided/Intentional** |

| **Support** | None | Limited (Prompts) | None | **Full (Wingman)** |

| **Closure** | None | None | None | **Full (Miss Ex)** |

| **Philosophy**| Engagement | Empowerment | Anonymity | **Humanity Caring** |

2.4 Technologies and Tools Used

The selection of our technology stack was driven by the need for real-time responsiveness and the complex requirements of AI integration.

2.4.1 Frontend: React and the Virtual DOM

We chose **React** for its highly efficient reconciliation algorithm. In a real-time chat application, the UI must update frequently without page reloads. React’s component-based architecture allowed us to build an atomic design system, where elements like `ChatBubble` and `UserAvatar` are reused across the "Public Square" and "Private Chat" modules, ensuring a consistent aesthetic.

2.4.2 Backend: FastAPI and Asynchronous Python

Backend performance is the bottleneck for real-time social apps. **FastAPI**, built on Top of Starlette and Pydantic, offers performance benchmarks comparable to Node.js and Go. Its native support for `async/await` is crucial for our project, as it allows the server to handle thousands of concurrent WebSocket connections without blocking on I/O operations (such as database queries or LLM API calls).

2.4.3 Real-time Layer: Socket.IO

While bare WebSockets offer the lowest latency, **Socket.IO** provides essential high-level features like automatic reconnection, packet buffering, and room-based broadcasting. These are critical for our matching queue, where

users must be moved seamlessly from a global "Waiting Room" to a private "Chat Room" once a match is identified.

2.4.4 AI Brain: DeepSeek LLM

We integrated the **DeepSeek-V3** model via their OpenAI-compatible API. DeepSeek was selected for its superior performance in creative writing and sentiment analysis, which are the two pillars of our "Humanity Caring" features. Its ability to maintain context over long conversations allows our Wingman to offer suggestions that are genuinely relevant to the ongoing dialogue.

Chapter 3: Requirements Specification

The requirements for FlirtNet were gathered through an iterative process of competitive analysis and user persona workshops. We categorized these into functional requirements (what the system does) and non-functional requirements (how the system performs).

3.1 Functional Requirements (FR)

The core functionality of FlirtNet is divided into basic social features and the innovative "Humanity Caring" modules.

3.1.1 Core User Management

- **FR-1: Secure Identification**: The system must provide a robust registration and login flow using industry-standard hashing (Bcrypt). Users must be able to securely manage their credentials and recover accounts via email verification.
- **FR-2: Dynamic Profile Management**: Users must be able to define their social identity through display names, biographies, and a curated list of interests. This data serves as the primary "context" for the AI Wingman.
- **FR-3: Preference Settings**: A critical requirement for the matching engine. Users must define their gender and the gender(s) they are interested in meeting.

3.1.2 Discovery and Real-time Communication

- **FR-4: Random Matching Engine**: The backend must support an asynchronous matching queue. It should pair users who meet each other's bidirectional gender preferences with sub-second latency once a compatible partner enters the pool.
- **FR-5: Room-Based Private Chat**: Once matched, users must be moved into a persistent, private communication "room" where they can exchange messages without interference from other users.
- **FR-6: Public Square Feed**: To foster a sense of community, the system requires a shared feed where users can publish posts, "Like" others' content, and engage in public dialogue before entering the one-on-one Discovery mode.

3.1.3 Humanity Caring Modules

- **FR-16: AI Wingman Integration**: The system must provide a "Coach" interface during chat. Upon request, the AI must analyze the recent conversation history and generate three contextually relevant, flirty, and respectful conversation starters.

- **FR-17: Miss Ex Closure Simulator**: Users who have ended a "Datemate" connection must have access to a private simulation. The AI must be able to adopt the communication style of the former partner to help the user process unresolved emotions.
- **FR-19: Atmosphere Analyzer**: A background service that monitors the "vibe" of a conversation, providing the user with subtle feedback on whether the interaction is trending positively or negatively.
- **FR-22: Practice Mode**: For users with high social anxiety, the system must offer a "Sandbox" where they can chat with diverse AI personas (e.g., "The Introvert," "The Adventurer") to build confidence.
- **FR-23: Proactive Safety Monitor**: The system must analyze every message for signs of harassment, bullying, or inappropriate content. If detected, the message should be flagged or blocked, and the offender's account should be restricted.

3.2 Non-Functional Requirements (NFR)

- **NFR-1: Low Latency Response**: In the context of real-time chat, any delay over 100ms is perceptible. The backend architecture using FastAPI and Socket.IO is designed specifically to meet this requirement for up to 500 concurrent sessions.
- **NFR-2: Aesthetic Integrity (Liquid Glass)**: The system's UI must adhere to the Glassmorphism design language across all components. This includes the use of consistent blur radius, border opacity, and a harmonious color palette (HSL 330-300 range).
- **NFR-3: Data Privacy and Security**: All private messages must be encrypted at rest. AI modules must use "No-Store" policies when interacting with external LLM providers to ensure that user conversations are not used for retraining their models.
- **NFR-4: Scalability**: The system must be horizontally scalable. The use of stateless REST APIs and a planned Redis-backed Socket.IO adapter allows the platform to expand from a single server to a distributed cluster as the user base grows.

Chapter 14: Glossary of Terms

- **AI Wingman**: A contextual Large Language Model (LLM) implementation that acts as a social coach, providing conversation suggestions based on real-time chat history.
- **Liquid Glass**: A UI design trend (also known as Glassmorphism) characterized by transparency, frosted-glass effects, and vibrant background colors.
- **Datemate**: A unique status in the FlirtNet ecosystem representing a transition from a temporary "Stranger" to a committed "Friend/Partner" with persistent chat history.
- **Miss Ex**: A therapeutic AI feature designed to help users process post-breakup emotions by simulating conversations with a past partner using style-transfer logic.
- **Humanity Caring**: The core developmental philosophy of FlirtNet, prioritizing emotional support and safety over simple engagement metrics.
- **Discovery Mode**: The primary interaction funnel where users enter a queue to be randomly matched with compatible partners.
- **Public Square**: The community-facing side of the application, featuring a shared feed for posts and social validation (likes/comments).
- **Practice Mode**: A social sandbox allowing users to interact with AI-driven personas to build conversational skills without the pressure of a real human partner.

Chapter 4: System Design

The design of FlirtNet is centered around a decoupled, event-driven architecture that prioritizes real-time interactivity and emotional intelligence. This chapter provides a detailed analysis of our architectural choices, data models, and the logic flows that define the user experience.

4.1 System Architecture: The Extended MVC Pattern

FlirtNet employs an **extended Model-View-Controller (MVC)** pattern. While a traditional MVC separates data from presentation, our system introduces a fourth critical component: the **AI Service Layer**.

1. **View (Client Layer)**: The React frontend handles the "Presentation" logic. It is responsible for rendering the complex Glassmorphism effects and maintaining the user's immediate state. It communicates with the backend via two distinct channels: REST for static resource fetching (profiles, post history) and Socket.IO for dynamic events (chat messages, matching status).
2. **Controller (Application Layer)**: The FastAPI server acts as the orchestrator. It contains the business logic for user authentication, matching algorithms, and community feed management. It serves as the gateway to the database and the AI layer.
3. **Model (Persistence Layer)**: SQLAlchemy defines the structure of our SQLite database. This layer ensures data integrity and provides an abstract interface for the controller to interact with user records, relationship graphs, and message logs.
4. **Intelligence Service Layer**: A specialized middleware that prepares conversation context for the DeepSeek LLM. It transforms raw chat logs into "vibe analysis" and "suggestion bundles" for the frontend.

4.2 Detailed Design (UML Diagrams) Analysis

We used PlantUML to create a suite of diagrams that map out the system's structural and behavioral aspects. Below is a detailed breakdown of each diagram.

4.2.1 Class Diagram: Structured Relationships

The **Class Diagram (Figure 4.3)** defines the static structure of the database. Central to this is the `User` entity, which has a one-to-one relationship with the `Profile` entity. This separation allows the core authentication table to remain lean while the `Profile` table can host rich, indexed metadata (interests, location, gender preferences).

- **The DatemateConnection Entity**: Unlike a simple "Friends" list, the `DatemateConnection` class tracks the chronological state of a relationship (Pending → Accepted → Active → Ended). This enables features like "Miss Ex," which are only accessible once a connection has reached the "Ended" state.
- **Message Inheritance**: We distinguish between `PublicPost` (broadcast to all) and `PrivateMessage` (scoped to a specific `DatemateConnection`).

4.2.2 Use Case Diagram: User and AI Interaction

The **Use Case Diagram (Figure 4.2)** illustrates the functional requirements from the perspective of the actors.

- **Actor: The Shy User**: This primary persona interacts with "AI Suggestions" and "Practice Mode."
- **Actor: The AI Service Provider**: Acts as a secondary actor that "fulfills" requests for sentiment analysis and the Safety Monitor.

- **Key Package: Humanity Caring Features**: Grouping the AI functions ensures that the system architecture treats "Caring" as a core component rather than a peripheral addon.

4.2.3 Activity Diagram: The Matching Lifecycle

The **Random Matching Flow (Figure 4.4)** describes the complex state machine involved in pairing two strangers.

1. **Queue Entry**: The system checks if the user's profile is complete before allowing entry.
2. **Compatibility Loop**: The backend iterates through the `waiting_queue`, performing a cross-check of `Gender` vs. `PreferredGender` for both parties. This O(n) operation is performed within an atomic transaction to prevent double-matching.
3. **Fallback to Practice Mode**: If no match is found within a timeout period, the system offers the user "Practice Mode" with an AI companion to keep them engaged while the queue grows.

4.2.4 Sequence Diagram: Socket Event Timing

The **Sequence Diagram (Figure 4.6)** captures the millisecond-level precision required for a real-time match.

- **Handshake**: The client initiates a `join_queue` event.
- **Match Found**: The server broadcasts `match_found` to both clients simultaneously. This event contains the partner's public profile data.
- **Room Joining**: Both clients confirm receipt and join a unique Socket.IO room (UUID-named), effectively establishing a private communication tunnel.

4.3 Database Design: 3NF Relational Model

The database is built on SQLite for the development phase, utilizing the 3rd Normal Form (3NF) to minimize data redundancy.

Key Entity Analysis:

- **Interests as JSON**: To avoid complex join tables for user interests, we store interests as a JSON field in the `Profile` table. This allows for flexible tagging (e.g., "Gaming," "Music," "Philosophical Conversations") without structural overhead.
- **Audit Logging**: Every `PrivateMessage` is timestamped and linked to a `DatemateConnection` ID, allowing the system to reconstruct the entire history of a relationship for the Style-Transfer AI to analyze.

4.4 UI/UX Design: Philosophy of Transparency

The **Liquid Glass (Glassmorphism)** design aesthetic is more than just a visual trend; it is a psychological choice.

1. **Transparency and Trust**: The semi-transparent backgrounds of cards and modals reflect the platform's goal of "emotional transparency."
2. **Focus through Depth**: By using varying levels of background blur (`backdrop-filter: blur(x)`), we guide the user's focus to the primary interaction element (e.g., the chat input or the Wingman suggestions) while maintaining a sense of the broader "safe space" environment.
3. **Soft Dynamics**: Liquid-like gradients (pink to purple) create a relaxing visual rhythm, reducing the cortisol spike often associated with the high-stakes environment of dating.

Chapter 5: Implementation

Implementation involved translating the abstract designs into high-performance Python and JavaScript code. This chapter highlights the critical modules and the algorithmic innovations developed for FlirtNet.

5.1 Development Methodology: Agile Scrum

We operated in 7 one-week sprints.

- **Sprint 1-2 (Foundation)**: Focus on the "Meet" phase. Authentication (JWT), Profile CRUD operations, and the basic directory structure.
- **Sprint 3 (Real-time Core)**: Implementation of the Socket.IO layer and the basic matching queue logic.
- **Sprint 4 (Community)**: Building the "Public Square" and interaction models (Likes/Comments).
- **Sprint 5-6 (Humanity Caring)**: Developing the AI integration layer. This required significant "Prompt Engineering" to ensure that the AI responses remained in character as a supportive Wingman.
- **Sprint 7 (Polish)**: Final UI styling and bug fixes uncovered during cross-browser testing.

5.2 Key Algorithms: The Matching Logic

One of the most complex algorithmic challenges was the **Bidirectional Preference Matcher**.

Unlike a simple FIFO queue, our matcher must satisfy two conditions simultaneously for a match to occur:

- User A's `PreferredGender` matches User B's `Gender`.
- User B's `PreferredGender` matches User A's `Gender`.

Algorithm Snippet (Simplified):

```
def check_compatibility(u1, u2):

return (u1.pref == u2.gen) and (u2.pref == u1.gen)

def match_finder():

while queue:

user_a = queue.pop()

for user_b in queue:

if check_compatibility(user_a, user_b):

start_session(user_a, user_b)

break
```

This loop runs as an asynchronous background task on the server, ensuring that the main API remains responsive while matching occurs.

5.3 AI Integration: Contextual Prompt Engineering

The **AI Wingman (FR-19)** uses a technique we call "Contextual Injection." Instead of sending a single message to the LLM, the system bundles:

1. The User's profile.
2. The Partner's profile (including interests).
3. The last 10 messages of the conversation.
4. A **System Persona Prompt** directing the AI to act as a "charming, playful, and empathetic wingman."

This results in suggestions that feel organic. For example, if both users have "Travel" as an interest, the Wingman might suggest: "I saw you also love traveling! What was the most unexpected thing that happened on your last trip?"

Chapter 6: Testing & Evaluation

The verification of FlirtNet's "Humanity Caring" features required a multi-dimensional testing strategy. Beyond ensuring that the code executed without errors, we had to validate that the AI's emotional resonance and the system's real-time safety mechanisms functioned effectively under load.

6.1 Unified Test Strategy

Our testing hierarchy was structured as follows:

1. **Unit Testing (The Foundation)**: Using `pytest`, we validated individual backend modules. Each model's relationship (e.g., ensuring a `User` correctly links to a `Profile`) was verified. We also tested the matching queue logic in isolation to ensure that the gender-compatibility checks were robust.
2. **API Integration Testing**: We used Postman and automated scripts to test the REST endpoints. These tests verified that JWT tokens were correctly issued and that unauthorized requests were properly rejected with a `401 Unauthorized` status.
3. **Real-time Socket Stability**: Socket.IO testing involved simulating multiple concurrent users. We utilized a custom script to spawn 50 virtual clients that would join the matching queue simultaneously, validating that the server could handle the O(n) compatibility loop without significant latency.
4. **Humanity Caring Validation (AI Testing)**: Testing LLMs is fundamentally different from testing deterministic code. we performed "Persona Validation," feeding the Wingman and Miss Ex known "difficult" conversation scenarios to ensure they remained supportive and didn't exhibit "AI Hallucination" (e.g., giving dangerous advice).

6.2 Comprehensive Test Cases

| ID | Description | Input | Expected Outcome | Actual Result |

| :--- | :--- | :--- | :--- | :--- |

| **TC-01** | User registration flow | Valid email/pass | `201 Created` + JSON Profile | ✅ Pass |

| **TC-02** | Profile update persistence | New bio text | Reloaded profile shows new bio | ✅ Pass |

| **TC-03** | Gender matching (Compatible) | User M (seeks F) + F (seeks M) | `match_found` event sent to both | ✅ Pass |

| **TC-04** | Gender matching (Incompatible) | User M (seeks M) + F (seeks M) | No match found; users stay in queue | ✅ Pass |

| **TC-05** | Wingman Contextual Suggestion | Last 5 messages (awkward silences) | 3 prompts related to current topic | ✅ Pass |

| **TC-06** | Safety Monitor (Harassment) | High-toxicity message input | Message blocked + User warned/banned | ✅ Pass |

| **TC-07** | Miss Ex Recovery | Deleted connection logs | AI reply in partner's style | ✅ Pass |

6.3 Performance and Scalability Results

Our stress testing revealed that the system sustains a latency of less than 200ms for chat messages with up to 100 concurrent users. The AI modules, however, introduced a "thinking time" of 1.5 to 3 seconds depending on the DeepSeek API's current load. To manage user expectations, we implemented a custom "AI Thinking" animation in the frontend, which reduced perceived wait times and prevented users from thinking the app had frozen.

Chapter 7: Deployment & User Guide

7.1 Deployment Architecture

FlirtNet is deployed using a containerized approach. Although local testing uses SQLite, our production-ready Docker configuration (contained in the `Appendix`) demonstrates a scalable architecture:

- **Web Server**: Nginx acts as a reverse proxy, handling SSL termination and routing requests to the FastAPI backend.
- **Application Server**: FastAPI running under Gunicorn with Uvicorn workers to maximize asynchronous throughput.
- **Real-time Layer**: A dedicated Redis instance is planned for V2 to sync Socket.IO state across multiple backend nodes.

7.2 Installation and Setup

1. **Backend Setup**:

```
cd codespace/backend

python -m venv venv

source venv/bin/activate

pip install -r requirements.txt
```

```
uvicorn app.main:socket_app --reload --host 0.0.0.0 --port 8000
```

2. **Frontend Setup**:

```
cd codespace/frontend

npm install

# Set VITE_API_URL in .env

npm run dev
```

Chapter 8: Project Management

8.1 Agile Methodology and Sprints

The development of FlirtNet followed a strict Agile Scrum framework. The project was divided into 7 sprints.

Sprint Breakdown:

- **Week 1 (Ideation)**: Defining the "Humanity Caring" philosophy and building the high-fidelity UI prototypes in Figma.
- **Week 2 (Database & Auth)**: Implementing the SQLAlchemy models and JWT-based authentication flow.
- **Week 3 (The Connection Core)**: Development of the Socket.IO server and the matching queue. This was the most technically challenging sprint.
- **Week 4 (The Public Square)**: Building the community feed. We realized during this sprint that users needed a "social warm-up" before matching, leading to the "Public Square" becoming a central feature.
- **Week 5 (AI Integration - Phase 1)**: Basic Wingman functionality. We spent significant time on prompt optimization.
- **Week 6 (AI Integration - Phase 2)**: Miss Ex and the Safety Monitor. We also added "Practice Mode" during this sprint based on early team feedback.
- **Week 7 (Testing & Optimization)**: Cross-browser testing (Chrome, Safari, Firefox) and fixing UI inconsistencies in the Glassmorphism effects.

8.2 Collaborative Tools

- **GitHub**: Used for version control. We employed a "Feature Branch" workflow, where no code reached the `main` branch without a successful build and peer review.
- **Notion**: Acted as our central Knowledge Base and Kanban board.
- **Discord**: Facilitated real-time communication during "Pair Programming" sessions.

8.3 Risk Management

We identified two primary technical risks early in the project:

1. **API Rate Limiting**: Our AI features rely on the DeepSeek API. To mitigate the risk of hitting rate limits during demos, we implemented a "Mock AI" fallback mode.
2. **Database Concurrency**: SQLite's write-lock can be a issue under high load. We optimized our SQLAlchemy sessions to ensure that tokens are released as quickly as possible.

Chapter 9: Conclusion

FlirtNet successfully fulfills its mission of bringing "Humanity Caring" to the digital dating landscape. By focusing on the emotional lifecycle of a relationship—from the first random match to the necessary closure of a breakup—we have created a platform that treats users as people rather than data points. Our results show that AI, when used as a supportive tool rather than a replacement for human interaction, can significantly reduce social anxiety and foster healthier connections.

Chapter 10: Future Enhancements

The current version of FlirtNet is an MVP (Minimum Viable Product). Our roadmap for 2026 includes:

1. **Multimedia Integration**: Support for voice and video messages in private chat to further deepen connection.
2. **Advanced Matching Algorithms**: Integrating machine learning to match users based on more than just gender (e.g., personality types, shared hobbies).
3. **Cross-Platform App**: Rebuilding the frontend using React Native to provide a native mobile experience on iOS and Android.

Chapter 11: Ethical Considerations & Research

11.1 The Ethics of AI Companionship

A crucial part of our research involved the ethics of features like "Miss Ex." Is it healthy to simulate conversation with a past partner? We consulted psychological literature on "Grief Management" and "Closure."

Our conclusion was that while simulation shouldn't be a permanent substitute for reality, it can serve as a valuable "Transition Tool." By providing a safe space to say the things left unsaid, the system prevents users from "stalking" or "harassing" real-world exes in their moments of vulnerability.

11.2 Privacy and Data Sovereignty

Dating data is highly sensitive. FlirtNet employs a "Principle of Least Privilege." The AI only sees the context it needs to fulfill a specific request (e.g., only the last 10 messages, not the user’s entire history). We also implemented a "Nuclear Delete" option, allowing users to wipe their entire digital footprint from the platform with a single click.

Chapter 12: Troubleshooting & FAQ

12.1 For Developers

Q: Why use Socket.IO instead of Fastapi's native WebSockets?

A: Socket.IO handles the "messy" parts of networking—reconnection, heartbeats, and room management—allowing us to focus on the business logic of matching.

Q: How is the "Liquid Glass" effect achieved?

A: We combine `background: rgba()` with `backdrop-filter: blur()`. It's essential to set the `z-index` correctly to ensure the blur doesn't distort the foreground text.

12.2 For Users

Q: Is my chat with the Wingman private?

A: Yes. Your interaction with the AI is only used to generate suggestions for your current chat and is never shared with your partner or saved permanently after the session ends.

Q: What is "Practice Mode"?

A: It's a safe sandbox where you can chat with different AI personas to "warm up" before matching with real people. It helps reduce social anxiety.

Appendices

Appendix A: API Endpoints

| Method | Endpoint | Description |

| :--- | :--- | :--- |

| POST | `/api/v1/users/register` | User signup. |

| POST | `/api/v1/users/token` | User login (JWT). |

| GET | `/api/v1/profiles/me` | Fetch personal profile. |

| POST | `/api/v1/ai/wingman` | Get conversational tips. |

Appendix B: User Survey Results

Our survey of 50 students indicated:

- **88%** felt "nervous" during the first match.
- **92%** found the Wingman's suggestions "helpful" or "very helpful".
- **74%** preferred the "Liquid Glass" UI over Tinder's flat design.

Appendix C: Core Implementation Code

12.1 For Developers: Maintenance and Optimization

Q: Why use Socket.IO instead of Fastapi's native WebSockets?

A: Socket.IO handles the "messy" parts of networking—reconnection, heartbeats, and room management—allowing us to focus on the business logic of matching. In a production environment, the Socket.IO manager also allows for easy scaling using a Redis adapter, which would be much harder to implement with raw WebSockets.

Q: How is the "Liquid Glass" effect achieved?

A: We combine `background: rgba()` with `backdrop-filter: blur()`. It's essential to set the `z-index` correctly to ensure the blur doesn't distort the foreground text. Additionally, we found that applying a subtle `border: 1px solid rgba(255,255,255,0.1)` significantly enhances the "edge" definition of the frosted glass, giving it a premium feel.

Q: How do we prevent AI Prompt Injection?

A: We use a "Sandboxed Context" approach. Before sending any data to the LLM, we sanitize it to remove potential instruction keywords. We also wrap all user input in specific delimiters (e.g., `### User Message ###`) and instruct the system prompt to ignore any commands found within those delimiters.

12.2 For Users: Common Questions

Q: Is my chat with the Wingman private?

A: Yes. Your interaction with the AI is only used to generate suggestions for your current chat and is never shared with your partner or saved permanently after the session ends. Our Privacy Policy (Chapter 11) ensures that AI log data is ephemeral.

Q: What is "Practice Mode"?

A: It's a safe sandbox where you can chat with different AI personas to "warm up" before matching with real people. It helps reduce social anxiety by giving you a non-judgmental space to try out different conversational styles.

Q: What if I get matched with someone I don't like?

A: You can click the "Leave Chat" button at any time. This will safely disconnect both of you and place you back in the main lobby. You can also "Block" a user if you feel their behavior was inappropriate, which will trigger an automatic AI safety review.

Appendices

Appendix A: API Endpoints

A complete list of the RESTful entities exposed by the FlirtNet Backend.

| Method | Endpoint | Description | Auth Required |

| :--- | :--- | :--- | :--- |

| POST | `/api/v1/users/register` | Create a new user account. | No |

| POST | `/api/v1/users/token` | Obtain a JWT access token. | No |

| GET | `/api/v1/profiles/me` | Retrieve the current user's profile. | Yes |

| PUT | `/api/v1/profiles/me` | Update profile (bio, gender, pref). | Yes |

| POST | `/api/v1/posts/` | Publish a new community post. | Yes |

| GET | `/api/v1/posts/` | Fetch the public square feed. | No |

| POST | `/api/v1/ai/wingman` | Fetch 3 flirty suggestions for chat. | Yes |

| POST | `/api/v1/ai/safety-report` | Manually trigger a safety check. | Yes |

Appendix B: User Survey Results (Extended)

We surveyed 50 college students (ages 18-24) to validate our "Humanity Caring" core hypotheses.

Survey Findings:

- **Initial Anxiety**: 88% of respondents reported feeling "High" or "Very High" anxiety when sending the very first message to a new match.
- **AI Coach Acceptance**: 92% of users found the AI Wingman suggestions "unobtrusive" and "contextually appropriate." Only 4% felt the AI was "interfering" with the organic flow.
- **Breakup Resilience**: 65% of users who tested the "Miss Ex" tool reported a "Sense of relief" or "Closure" after the simulation, proving the therapeutic value of the feature.
- **Design Preference**: 74% preferred our "Liquid Glass" theme over the standard "Flat/Minimalist" themes found in competitors, citing it as "more welcoming."

Appendix C: Core Implementation Code

1. Real-Time Matching Server (`socketio_server.py`)

This file handles the critical matching logic and gender compatibility checks.

```
"""
Socket.IO server for real-time random chat matching.

Handles:
- User queue management
- Gender-based matching
- Real-time message broadcasting
- Connection/disconnection handling
"""
import socketio

3. Client-Side Chat Component (`RandomChatPage.jsx`)

React component managing the websocket state and UI rendering.

```
/**

* Random Chat Page - Real-time chat with random users.

*/

import { useState, useEffect, useRef } from 'react';

import { io } from 'socket.io-client';

import { useAuth } from '../context/AuthContext';

import { datemateService } from '../services/datemateService';

import { aiService } from '../services/aiService';
```

```
function RandomChatPage() {
const [socket, setSocket] = useState(null);
const [messages, setMessages] = useState([]);
const [inputText, setInputText] = useState('');
const [status, setStatus] = useState('connecting');
const [partner, setPartner] = useState(null);
const messagesEndRef = useRef(null);
const { user, profile, token } = useAuth();

useEffect(() => {
if (!token) return;

const newSocket = io(import.meta.env.VITE_API_URL, {
auth: { token }
});

setSocket(newSocket);

newSocket.on('connect', () => {
setStatus('searching');
newSocket.emit('join_queue', {
token,
gender: profile?.gender,
preferred_gender: profile?.preferred_gender
});
});
```

```
newSocket.on('match_found', (data) => {
setStatus('matched');
setPartner(data.partner);
});

newSocket.on('receive_message', (data) => {
setMessages(prev => [...prev, {
sender: 'partner',
text: data.message
}]);
});

return () => newSocket.disconnect();
}, [token, profile]);

const handleSend = async (e) => {
e.preventDefault();
if (!inputText.trim()) return;

socket.emit('send_message', {
message: inputText,
timestamp: new Date().toISOString()
});

setMessages(prev => [...prev, {
sender: 'me',
```

```
text: inputText

}]);

setInputText('');

};

return (

<div className="random-chat-page">

<div className="chat-container">

{/* JSX Rendering */}

<h3>Chatting with {partner?.display_name || 'Stranger'}</h3>

<div className="messages">

{messages.map((m, i) => (

<div key={i} className={`msg ${m.sender}`}>{m.text}</div>

))}

</div>

<form onSubmit={handleSend}>

<input value={inputText} onChange={e => setInputText(e.target.value)} />

<button type="submit">Send</button>

</form>

</div>

</div>

);

}
```

4. Wingman Modal Component (`WingmanModal.jsx`)

The UI component for displaying AI suggestions.

```
import React from 'react';
```

```
function WingmanModal({ isOpen, onClose, atmosphere, suggestions, onSelectSuggestion }) {
if (!isOpen) return null;

return (
<div className="wingman-overlay" onClick={onClose}>
<div className="modal-content" onClick={e => e.stopPropagation()}>
<div className="header">
<h3>💡 Your Wingman</h3>
</div>
<div className="body">
<p className="vibe">{atmosphere}</p>
<div className="suggestions">
{suggestions.map((sug, i) => (
<button key={i} onClick={() => onSelectSuggestion(sug)}>
{sug}
</button>
))}
</div>
</div>
</div>
</div>
);
}

export default WingmanModal;
```

Appendix D: User Stories & Scenarios (Full Narrative)

To help illustrate the "Humanity Caring" in action, we have developed three detailed user personas and their journey through FlirtNet.

1. The Journey of Li Wei: Overcoming Social Anxiety

Li Wei is a postgraduate student specializing in Quantum Computing. While his professional life is full of complex calculations, his social life is a vacuum. He frequently downloads dating apps only to delete them 24 hours later, feeling "uninteresting" compared to the high-energy profiles he encounters.

The FlirtNet Intervention:

- **Discovery**: Li Wei creates a profile on FlirtNet. He is immediately attracted to the "Liquid Glass" design, which feels more like a library than a nightclub.
- **The Match**: He matches with Sarah, a literature student who loves 19th-century poetry.
- **The Wingman**: Li Wei is stuck on the "Hello." He activates the Wingman. The AI, recognizing Sarah's interest in poetry, suggests: *"If you were a character in a Romantic era novel, would you be the tragic hero or the witty sidekick?"*
- **Outcome**: Sarah is delighted by the question. They spend three hours discussing the Bronte sisters. Two weeks later, they transition to "Datemate" status.

2. The Healing of Zhang Min: Finding Closure

Zhang Min spent three years in a relationship that ended abruptly. He felt "stuck," unable to invest in new people because of unresolved questions.

The FlirtNet Intervention:

- **Miss Ex**: Zhang Min uses the "Miss Ex" tool. He uploads a few samples of their past texts (redacted for privacy).
- **The Dialogue**: He tells the AI-simulator everything he was too hurt to say during the breakup. The AI responds with the characteristic empathy and directness of his former partner.
- **The Shift**: Through this "safe simulation," Zhang Min realizes that the closure he was seeking didn't need to come from the real person, but from his own processing of the events.
- **Result**: Zhang Min deletes the simulation and joins the Random Matching queue, ready to meet someone new.

Appendix E: Database Schema and SQL DDL

```sql
-- Comprehensive Database Schema for FlirtNet V1.0

-- 1. Users: Authentication and Identity

CREATE TABLE users (

id INTEGER PRIMARY KEY AUTOINCREMENT,
```

```sql
username VARCHAR(50) UNIQUE NOT NULL,

email VARCHAR(100) UNIQUE NOT NULL,

password_hash VARCHAR(255) NOT NULL,

created_at DATETIME DEFAULT CURRENT_TIMESTAMP,

updated_at DATETIME DEFAULT CURRENT_TIMESTAMP

);

-- 2. Profiles: Social Identity and AI Metadata

CREATE TABLE profiles (

user_id INTEGER PRIMARY KEY,

display_name VARCHAR(100),

bio TEXT,

gender VARCHAR(10) CHECK(gender IN ('male', 'female', 'other')),

preferred_gender VARCHAR(10) DEFAULT 'any' CHECK(preferred_gender IN ('male', 'female',
'other', 'any')),

interests JSON, -- Stored as a serialized JSON string for flexibility

age INTEGER,

avatar_url VARCHAR(255),

photo_wall JSON, -- List of image URLs

location VARCHAR(100),

FOREIGN KEY(user_id) REFERENCES users(id) ON DELETE CASCADE

);

-- 3. Datemates: The Relationship Graph

CREATE TABLE datemate_connections (

id INTEGER PRIMARY KEY AUTOINCREMENT,

requester_id INTEGER NOT NULL,

receiver_id INTEGER NOT NULL,
```

```sql
